REASON # 6: TOO LITTLE SAFETY

Odds of a major nuclear disaster are said to be on the order of 1 in 10,000 reactor-years, but experience shows accidents occur even more frequently. Operation of some 1,500 reactors needed for nuclear power to play a meaningful role in reducing carbon emissions could result in a Fukushima-scale nuclear accident every five years—a price the world is not likely to be willing to pay. And more reactors means more potential terrorist targets.
